Ground Source Heat Pumps - You should Look for Professional Advice to Find the Correct Use of These Machines! by EnergyPR

Article published on December 5th 2011 | Science

If your ground source heat pumps is not responding in an anticipated way, then you should prefer hiring the experts to make it correct. Keeping the heat pump's function correct can also allow you to save more on the energy bills and at the same time, you can make your rooms cozy as well as comfortable during the winter.

Before you opt for the ground source heat pumps, its often essential to determine, what are they and how they function? Knowing more details about these equipments or machines will allow you to receive maximum benefits. at the same time, you can make the right use of these heat pumps simply by knowing their functionality. So, what are the ground source Heat Pump ? You might have heard about the heat pumps, but you may not know that the refrigerator and the air conditioners you are using at home also considered as the heat pumps. As far as the functionality of the Ground Source Heat Pumps is concerned, these pumps can often transfer the heat present at the ground level and emits it for the house or building that needs to be heated. In this way, these machines can actually work in an efficient way to perform space heating. These machines are also useful for preheating the water.

But how the ground source heat pumps use to work actually?

Different lengths of pipe are buried into the ground. These pipes are often buried with the help of the trench or the borehole. These pipes are filled with the mixture of antifreeze as well as water. This sort of mixture is then pumped across the pipes and they start to absorb the heat present at the ground. The heath pump often comprises of three main components.

The ground source heat pumps also feature these three components like the usual heat pumps. The evaporator use to absorb the heat in the water located at the ground level. Then the compressor use to compress the refrigerant which is often gaseous in nature and allows it to acquire the specific temperature. This temperature is further used for the real heat distribution across the circuit. Well the final component of the ground source heat pumps is the condenser. This portion use to transmit the heat for the tank of hot water and then it feeds the system assigned for distributing the heat. If you will look at the backside of the refrigerator, then you can find the condenser as a hot part.

A ground source heat pump can use the earth or the ground water or sometime both as the heat source during the winter. The earth or the ground water is the ultimate destination for heat to escape from home during the summer time. Heat will be acquired from earth through water. Sometime antifreeze solutions are also used instead of ground water for this process. Then the pump will upgrade as well as transfer the liquid into the indoor air. Well, this is definitely a unique method. This process is often adopted during the winter. And during summer the same process will work in a reverse fashion.
