DNA Synthesizer is Very Handy by James Blee

Article published on April 28th 2012 | Advertising

To get a proper understanding of the DNA synthesizer, it becomes necessary to know the role it plays in a number of different DNA analysis techniques that are usually adopted. One such example is the RFLP or Restricted Fragments Lengths Polymorphism.

Under this process, the investigators are often compelled to dissolve DNA. This is done with help of an enzyme which in turn helps in breaking the strands into specific points. Because the number of repeats affect the resultant strand of DNA, these investigators take help of the DNA synthesizer.

One market survey conducted by a leading manufacturer of such synthesizer has thrown some interesting observations in to the open. For instance, it is the laboratories who are the greatest users of oligonucleotide synthesizer.

It may be noted, the laboratories are not the ones who benefit from making use of dna synthesizers. On the contrary, the same survey has found that a majority of jurors in courtrooms across the country do not shy of from relying on findings of these synthesizers. The kind of popularity that this device has received is more than what happened when finger print analysis came into the picture for the first time.

With changing times, the nature and types of crimes that happen these days have become very complicated in nature. This is where the role of DNA analysis has replaced the previous finger print analysis. In fact, DNA analysis arrived at after making use of these synthesizers has successfully replaced the effectiveness and reliability of finger print analysis. It has given a clear helping hand to criminal investigators which explain why they have them able to solve many crime investigations with ease and comfort. The synthesizers that are used are fully incorporated with fantastic features which have enough touches of new-age technologies. This is one reason why it has found immense popularity among users.
