A brief overview on the environmental remediation by Tory Black

Article published on March 13th 2012 | Marketing

The environment is tortured every moment by the pollutions that are happening all over the world. Unless we protect our environment, there will soon be a time when human beings and other form of life would cease to exist in this world. And this thought has led all the environmental consultants all over the world to think of a process for environmental cleanup.

It is also known as the environmental remediation that restores the contaminated part of the environment into a fresh state that is free of pollutions in all forms and that is also absolutely safe for the human beings and other living beings of the planet.

The environmental remediation in most cases involves the media such as the sediment, surface water, soil, and ground water. There are many latest technologies involved in the environmental cleanup. But before deciding on the technology for usage, you must opt for a complete environmental assessment for the polluted site.

There is also a process of excavation or the dredging where the contaminated site is dug up and then transmitted to some regulated dump sites. Another process is the surfactant enhanced aquifer remediation where some special form of surfactants or hydrocarbon mitigation agents is injected on the surface of the soil. These agents reduce desorption thereby speeding up the process of clean up.

In case of the ground water cleanup, it is pumped out and treated for pollution via a series of recovery vessels. There is also solidification and the stabilization process in which various forms of reagents are added to the polluted material and turn it into a chemically stable material. In case of the solidification, the reagents are added to the contaminated materials to make it stable physically thereby limiting the access of the materials to the external agents like the rain and air.

Some of the environmental remediation techniques that are applied for environmental cleanup can easily be classified into the in-situ method and the ex-situ method. The affected soils are first excavated and then the surface is treated with the ex-situ method. In case of in-situ methods, the pollution is treated without removal of the soil and then it is given a restored set up.

Bioremediation is a defined process that makes use of the micro organisms or enzymes to restore the polluted sites into its previous state. It is an eco friendly process and is a popular approach with the environmental consultants.
