Article published on April 18th 2012 | Business

A motor vehicleâ€™s speed is automatically controlled by a system, which is known as cruise control. When a driver sets the speed this system helps to maintain the speed by controlling over the throttle of the car. Most of these cruise or speed control systems do not work below a certain speed.

This is the reason why in case of congested traffic conditions these systems do not come in use. In the congested conditions, speed varies widely and the system loses control over the same after a certain period. On the other hand, in steady traffic conditions, these systems work for driver comfort & improvement technique.

This speed or cruise control system plays a vital role in controlling the speed set by the driver. It helps the driver to stop looking at the speedometer even when he is busy in handling the critical traffic conditions. This system works as an added feature for the automobiles. However, it is worthwhile to mention here that before driving you must check the condition of the system on regular basis. You might find it not working properly which means a visit to the mechanicâ€™s shop is required. It may happen due to a short in the system or if a wire is disconnected. These are regarded as minor problems, which can readily be fixed without wasting much time.

Like the speed control systems there is another object that people find very useful these days which is a energy received from the direct sunlight. This energy is captured from the sunlight and thereafter the same solar energy is converted with the help of mechanical source. The mechanically built materials that are randomly used for residential as well as commercial purposes are known as the solar panels. With the advent of technology, thus the solar energy is used to serve the humankind as the electrical energy.
