Article published on July 27th 2012 | Business

Have a lot of junk accumulated at the construction site? However, in between the junk there might be some important things, which can be put to good use later. Therefore, before the junk is disposed of will it would not be an ideal solution if things are sorted out. Hence, one will require the services of a picking stations. These stations can be static or mobile. It is the ideal place to screen the junk before they are finally disposed off. The stations are quite large. The normal height is around 3.5m and the interior area is 55 yards approximately.

If there is a need for one, there are plenty of manufacturers who manufacture these stations. If there are some personal requirements one can always get it specially done to suit their individual needs. One can even opt for some special design if the situation demands so. There must be paid special attention to the number of picking bays one gets with each of these stations. To make the sorting operations comfortable one is bound to come across stations where the comfort factors such as proper lightning and heating have been installed. If there is a need to remove ferrous metals an over band magnet is installed. The most important thing is that these stations may be mobile or even static.

However, if there is a need to remove minute particles one can always consider using the Screen Spares technology. This technology is used in the quarrying, sand and gravel construction and waste recycling process. The end product in most cases is of high quality. Hence, it is all about applying a proper technology to make sure that anything valuable is sorted out before the junk is disposed off. The goods, which have been recovered from proper screening now can be recycled and presented in a different form. This is a much better option than going for the traditional landfill, which at some stage may led to increase of pollution.
