Data logging and retrieving information in Less than Five minutes by Julia Roger

Article published on July 10th 2012 | Computer

Here the article deals with different ways in which you can do data logging that too within 5 minutes. Data logging is possible through simple methods of using embedded controller or data logger or acquisition modules connected to your PC. The systems take only about 5 minutes to get all set up.

In less than five minutes

Configure Datalogger with the PC. Set them up at desired interval, for instance in every 5 minutes. Now, leave the system for 5 days at a stretch. After five days is over connect the data logger to the PC and retrieve all the information that is required. Using the data collected, spread them through the spreadsheets where you get to analyze the same. The eventual result is that you get to forecast what the possible future humidity and temperature would be.

Use a data acquisition module to log data. The process helps in collecting information on voltage, humidity, temperature and current. The process is carried by connecting sensors to the possible terminal block on the various acquisition modules. However, the quantity of information you can boot on to the PC depends upon the memory size of the PC. The remarkable thing is that it can be done in 5 minutes.

Use a wireless host converter and connect it to the PC. Thus, the data acquisition module will help in communicating with the PC through wireless. It is the technology that uses to turn on or off the lights. Eventually you get to analyze information and catch all the trends. It will help you in figuring optimal solution that helps in saving a great deal of energy.

Thus, by now, you know how the data logger system helps in learning about whether and temperature and also energy in less than 5 minutes that eventually help in expanding knowledge and learn a great deal.
