Coffee Machines - What Differentiates Them

by Lidya Ivanova

Article published on April 23rd 2012 | Food

There are many types of coffee makers today, and each of them is made by a different manufacturer. Therefore, they are usually different from each other. Some of the differences are usually open and well known, such as the size of the machine, or the amount of coffee that they can make in an instant, or where the coffee is taken after being brewed - in a cup, flask and so on. However, there are also other differences that cannot be seen, but are still there nonetheless.

So, if you are wondering what is different about your Coffee Machine, and other that you have seen around, then this includes:

Water Source

There are some coffee makers that usually get hot water from a separate source, the French press maker, and there are other makers which usually use either hot or cold water depending on the type of coffee that one wants. Yet still there is another maker that usually has a filter, and this usually makes coffee directly on a mug.

Therefore, there are various types of makers that use various sources of water. The brew that is usually made from these various sources is however normally the same, although there are people who usually say that they can tell the various styles used in coming up with the brew.

However, it has been known that water that is preheated usually makes some of the best coffee today.

Pumping System

There are many types of coffee makers today. They are usually classified as automatic, manual, or even semi- automatic. All these use various mechanisms to work, and people usually choose the type that they want on their Coffee Machine.

A manual pump machine usually requires that a person uses manual labor in order to operate the maker. This is one of the most common makes of coffee machines, and it usually requires that someone loads up the water and coffee ground ends and also determines the time that the brew will be made. On the other hand, an automatic pump is quite the opposite. This is because it works automatically, all a person needs to do is simply switch it on, and the coffee can be brewed. Therefore, a person does not regulate the time the brew is made, or even the amount of water passed through the ground.

The semi-automatic brew is a great Coffee Machine that is usually used to ensure that a person can regulate water flow and time although they do not really have to operate the machine. The cost of these various machines usually differs with the manual machines being the most expensive.

These are just two main differences of coffee makers in use today. It is advised that consumers know the various types today because all these differences usually mean that a person will not get the same brew from the different makers.

Nonetheless, if you are looking to buy a Coffee Machine, it is advisable that you carry out some research so that you can be certain that you will be able to get a great machine for your use.
