Article published on April 12th 2012 | Home Improvement

With the mercury rising every single minute, it tends to pull out your energy and makes you long for a solution which will help you stay cool throughout this summer. The Air Conditioner seems to be one of the best innovations of mankind. There is a variety of air coolers available in the market today. There are basically two types widely available. The first variety uses the power of water to function and the other type called air cooled chiller is durable and does not consume as much energy as the ones that run on water. These can be easily mounted on the top of a window or wall. Most of the industries prefer this type of cooling device for their offices and workplaces as they are easy to use.

The air cooled chillers cool the air around us and makes us comfortable throughout the time it is operating. The technology used in our refrigerators is the same as the one used in these coolers. The biggest component that this device uses to cool the surrounding area is water. Though they do not use as much water as a cooler which operates on water, this does have to use quite an amount to function. The chiller is made up of tubes which are filled with water, an evaporator and a condenser. These three components play a significant role in ejecting cold air into the surroundings. Also, just the mere purchase of air cooling apparatus does not mean that you do not maintain it once you get it installed. The main task after using the cooler is to keep it well maintained by servicing it from time to time, which will increase the longevity of the system.

There is a range of new cooling system known as the HVAC. Wondering what that means? The full form of this is Heating, Ventilation and Air Conditioning. These three are the basic components needed to control the varied temperatures of your house,industries and units under control. As cold air plays a significant role in keeping the temperatures in check, the heating and ventilation also play a pivotal role. If it gets too hot it can lead to a heat stroke and also leave you completely dehydrated and fatigued. If heat is not supplied to the body it can lead to hypothermia. Also, if your house or your work area is not ventilated properly, it can lead to a number of allergies. So the HVAC air conditioning system does three important things for you- it regulates humidity, air flow and the room temperature.

With an easy installation you can fight all these problems with just one solution. The heat can be troublesome and spoil things in your office, home and also do bodily harm. At such times the cooler takes care of the heat by turning the present hot air into a cooler one. When it gets too chilly, you need some device to make the surrounding area comfortably warm. A heater, should ideally be placed at the centre so that it can warm up the whole room in less time than that of a locally placed one. Also, ventilating and cleaning your house and workstations time to time to eliminate the dust, mites and other small bugs from your home and work stations, is a good practise.

So, planning to buy a HVAC air conditioning system? What are you waiting for? Research online and just go for it as its worth investing this summer.
