Wood Stoves for Saleâ€”Essential Features

â€¢ A wood burning stove is basically a completely enclosed metal container or box. Naturally, a lot of heat energy would be required for elevating its temperature, specifically, if its body is made from cast iron. So, you would have to be prepared to invest quite some time for the heating to begin.

â€¢ The wood burning stoves would be equipped with one or more valves in order to control the intake of air. These would include the primary air input valve and the secondary air input valve. The primary air input valve would bring in cold air from its surroundings, under the blazing wood. The secondary air input valve would take the air that has already been circulated around the heating stove and over the viewing glass in the front, also helping in soot removal.

â€¢ The secondary air is already hot when it blends with the hot air emanating from the blazing wood. So it becomes easier for the gases in the upper part of the box to ignite, making it hotter and releasing more of heat energy. This makes it more efficient in comparison to the traditional wood fire.

â€¢ If you are looking for a more efficient heater that can covert the fuel to heat energy relatively faster in comparison to an ordinary wood fire, these wood stoves should certainly be your pick.
