There are several of concerns or troubles we might find in any computer. Troubles such as driver issues, hardware problems, blue screen of death, computer freezing, alarming pop ups, virus infection; driver issues, hardware problems, blue screen of death and so forth are very general and can be seen simply in any computer. Though the slow PC issue is the chief and wide extend crisis we may face in our day. Despite of vast hardware changes or good arrangement in hardware, very high memory power or random access memory and hard disc drive a PC becomes poor and sluggish in performance. I have felt that growing size of new programs that are coming in the marketplace today is also liable for a slow PC problem. In windows xp the mandatory RAM size used to be 256MB which enlarged to 512 in windows vista and now 1GB advised by Microsoft now for windows 7 PCs. Not only this even application software's size have also been improved radically and due to this these programs take profound usage of memory and processors time. In truth if you run only the basic programs such as ms office an antivirus and few other significant programs, the slow PC issue occurs very less reasonably. As a result we may also bring to a close that enormous programs present in a PC are also accountable to generate slow PC problem separately from other reasons.

In my own experience of passed 5 years this slow PC issue there isn't any specific basis. There are plentiful or countless factors that make a PC slow or produce a slow PC problem in any PC. I have written few important of them here below.

1. Virus infection- one of the most severe causes behind slow PC problem is a virus infection in your PC. Viruses not only create this slow computer problem but also affect your PC many ways. Stopping all the normal operations can also be caused by a virus program. I am reminded for past few years there was a series of viruses named antivirus 2008, antivirus 2009, antivirus 2010 antivirus 2011 etc. Every year there was a new virus program introduced and that used to cause panic in any windows operating system. Later there were some removing instruction available for this series of virus but in the beginning these viruses used to stop the entire system and we don't have any option but to format the entire OS and reinstall. So an extra care needs to be taken if severity of a virus program is very high.
2. Spyware- Unlike a virus programs these software routines or programs do not harm PC that badly but they are more dangerous in a way that they steal sensitive and important information from your computer. If their number is very high they also can cause slow PC problem in your computer.
3. If too many unneeded programs are installed in a PC- If there are a number of programs installed in a PC they divergence each other and try consuming greatest resources such as CPU usage, Random access memory hard disc space etc as much possible.
