How to fix the registry errors of slow computer by [Hennary Joe](#)

Article published on January 5th 2012 | [Software](#)

A slow computer is a real issue for all PC users. There are various reasons behind making a PC slow. Few of the causes are common for many issues in your PC. For an example if your hardware is not compatible or if there is an infection in the PC it will not only make a PC slow rather it can also create some other issues as well, such as freezing, blue screen, alarming pop up messages on the display screen etc. There is one more strong reason behind making PC slow or creating many other issues and that is corrupted, bloated registry in your PC. A good windows registry booster program can help you to make you registry intact and fit. It is also noted that in most of the cases where an infection is found it affects your windows registry and make it unstable and corrupted. A registry booster scans and repairs all the corrupted values in the registry and subsequently PC makes faster. However apart from windows registry there are certain few more causes or areas where problem can be found and which can affect a PC severely. I want to write few of them today.

Hardware is not compatible- If you are using poor or incompatible hardware that are not meeting the requirement to run the application of system software, in such cases it reduces PC's overall performance and you may experience slow PC issue. Apparently there isn't any alternate for hardware issue and you need to replace the affected or corresponding hardware part. Memory is one of the greatest examples of insufficient or incapable hardware issue.

Infection in your PC- Infection makes PC affected in many ways. A virus is foremost among all the infections. There are few viruses that completely stop PC's total doings and sometime we may need to format our PC. Officially an antivirus program is the ultimate solution for removing any virus program but sometime we might need to go to some extra miles to remove it. That is sometime merely an antivirus does not help and a manual interference is needed.

Reduce visual effects in your PC- Windows is rich at graphics and reducing these graphics helps immensely. Try reducing the graphics and see the difference.

Clear all the temporary files and system dump files from your PC- Over time if you continue using your PC and do not clear the temporary files and some system created dump files they occupy unnecessary space in the hard drive and reduce overall performance of your PC. Clear these files in a regular interval.

Registry corrupted/bloated in your PC- As I said before also a registry is very integrated part of any PC and if it gets corrupted it formulates many issues like freezing, blue screens, alarming pop up error messages, and overall system down performance. Use a good registry booster program in order to correct or repair all the errors or to repair the entire registry system.
