Article published on February 25th 2012 | Technology

Choosing the projector screen material is very important when you want excellent image quality. The quality of the image also depends on the kind of lighting available. A good screen can give you a better image with a greater contrast, detail and depth to the image. When you choose the projection screen material there are a few things that need to be taken care of. It is important to pick and choose materials that have the capability to reflect more colors in the light spectrum. Moreover, these materials are ideal for different contrast levels, from no contrast or light contrast to medium and high contrast levels. There are many different types of projectors which handle contrast, colour and brightness differently too.

When you are picking the material for projector screen, you should pick something that can normalize the color balance and produce subtle shifts in the reflection of the image produced. You need to check for materials which offer different types of features for example, on exaggerating blue, red or green shades. It is important to pick the color of the screen wisely as well. There are white and grey screens, the latter providing you the contrast you need for darker colors perfectly.

An important feature that you must have in the screen material is that light should not be permitted to pass through from the other side. If you go for something inexpensive, this could turn out to be an issue where you will not get the depth and detailing in the image and instead see something that looks light and faded. Some people also pick fabrics from stores so that they can create the projector screen themselves with several blackout materials available to pick. Matte fabrics could also give you a good performance. Vibrant life like colors are needed for movies, so what you will watch is also important.
